Abstract— A description of the beta decay of the nucleus \( \text{Dy}^{168} \) is presented using the Gamow-Teller force in the frame of the proton-neutron Quasiparticle Random Phase Approximation (pn-QRPA). The single-particle ground states are obtained self-consistently using the Fayans energy density functional in an HFB scheme, and the quasiparticle states are built on the single-particle ground states using the BCS approximation. The calculation gives two Gamow-Teller transitions as expected, a half-life about one third of the experimental value, and a decay energy close to the experimental value.

Keywords— beta decay, Gamow-Teller force, proton-neutron Quasiparticle Random Phase Approximation.

I. INTRODUCTION

Since its invention many years ago [1], the proton-neutron Quasiparticle Random Phase Approximation (pn-QRPA) has remained the only microscopic approach available for beta decay calculation in heavy nuclei; however, it suffers from poor accuracy. Thus, the extensive work by Staudt et al. [2] using the so-called second-generation microscopic method has reproduced half-lives for about 96% of all known neutron-rich nuclei with half-lives \( \leq 60 \) s within a factor of 10, with an average half-life ratio \( r = 1.67 \); however, their use of a simple separable Gamow-Teller force is far from satisfactory from the theoretical point of view. Meanwhile the Hartree-Fock-Bogoliubov (HFB) method is known until now as the most general approach for the calculation of the nuclear ground state [3], and the first self-consistent ground state calculation of this type on deformed nuclei, using the so-called Fayans energy density functional ([4],[5]) has been performed by Kroemer et al. [6]. The self-consistent nuclear ground states obtained by the HFB method using this functional have been applied by Borzov et al. [7] as a basis for the calculation of beta decay half-lives in spherical nuclei using the self-consistent BCS+pn-QRPA method.

This paper uses a similar approach as in [7], however the present model employs a different interaction to obtain the excited daughter state, and the subnucleonic excitation, which was taken into account in Ref. [7], is neglected since we deal with low energies in the order of 1 MeV. The present model has been developed for the calculation of beta decay of the Gamow-Teller mode in even-even nuclei. It is interesting to apply the use of a Gamow-Teller exciting force to the description of more complex beta decay containing not only Gamow-Teller transitions, and the \( \beta^- \) decay from \( \text{Dy}^{168} \) to \( \text{Ho}^{168} \) meets the criteria since it contains two Gamow-Teller transition plus a \( 0^+ \rightarrow 1^+ \) transition with an overall decay energy of 1.4 MeV, as can be seen from Figure 1 [8].

II. Theory

The Fayans energy density functional may be expressed as a functional of the particle normal density $\rho$ and the anomalous density $(\nu, \nu^\dagger)$,

$$
E[\rho, \nu, \nu^\dagger] = \int d^3r \left[ \varepsilon_{\text{kin}} + \varepsilon_{\text{vol}} + \varepsilon_{\text{sur}} + \varepsilon_{\text{coupl}} + \varepsilon_{\text{iso}} + \varepsilon_{\text{pair}} \right],
$$

(1)

where the terms in the integral are the kinetic, volume, surface, Coulomb, spin-orbit and pairing energy densities, respectively. The sum of all energy density terms except $\varepsilon_{\text{kin}}$ is called the interaction energy density. The Fayans density functional contains Fermi parameters such as the particle density in symmetrical nuclear matter at equilibrium, $2\rho_0$, the Fermi momentum, $p_F^0$, the Fermi energy, $E_F^0$, the sum and the difference between the proton and neutron relative densities

$$
x_k = \frac{\rho_n^k \pm \rho_p^k}{2\rho_0},
$$

(2)
as well as their functions and derivatives,

$$
f_k = \frac{1 - h_{k+} x_k}{1 + h_{k+} x_k}, \quad f' = \frac{d}{dx} f(x_k),
$$

(3)

where $h_{k+}$ and $h_{k-}$ are parameters of the functional. The single-particle potential and the strength of the two-nucleon p-h interaction may be derived from the derivative of the interaction energy density with respect to particle density $\rho$, while the particle-particle (p-p) interaction may be derived from the derivative of the pairing energy with respect to pairing (anomalous) densities $(\nu, \nu^\dagger)$.

In HFB theory one looks for the most general product wave functions consisting of independently moving quasi-particles. Within this approximation, the Hamiltonian reduces to two average potentials, the self-consistent field $\Gamma$, which is already known from the Hartree-Fock theory, with matrix elements

$$
\Gamma_{q\ell} = \sum_{q\ell'} \tilde{V}_{q\ell q\ell'} P_{q\ell'},
$$

(4)

and an additional pairing field, $\Delta$ known from the BCS theory with matrix elements

$$
\Delta_{q\ell} = \frac{1}{2} \sum_{q\ell'} \tilde{V}_{q\ell q\ell'} V_{q\ell'}.
$$

(5)

The field $\Gamma$, also called the normal pairing potential, contains all the long-range p-h correlations which eventually lead to a deformed ground state, whereas the field $\Delta$, also called the anomalous pairing (tensor) pairing potential, sums up the short-range pairing correlations that can lead to a phase transition and a superfluid state. The BCS quasi-particles is a special type of quasi-particle defined by a special Bogoliubov transformation. Even though $\Gamma$ (and $h = t + \Gamma$, with $t$ kinetic energy) is not diagonal, it is convenient to define single-particle energies by

$$
\varepsilon_k = h_{k+} \varepsilon_k.
$$

(6)

Analogously one may define single-particle energy gap parameters by

$$
\Delta_k = \Delta_{k+} \varepsilon_k.
$$

(7)

It is convenient to define an average pairing gap in the neighborhood of the Fermi level by averaging the values of $\Delta_k$ directly above and below the Fermi level,

$$
\Delta_p = \frac{\Delta_{p+} + \Delta_{p-}}{2}.
$$

(8)

The HFB ground state eigenfunctions are obtained by solving the HFB equations

$$
\begin{pmatrix}
\hbar^2 \Delta

\hbar^2 \Delta^* - h^* & U_k \\
-\Delta^* - h & V_k
\end{pmatrix}
= E_k
\begin{pmatrix}
U_k \\
V_k
\end{pmatrix},
$$

(9)

where $h = \varepsilon + \Gamma - \lambda$, $\varepsilon$ and $\lambda$ are respectively the single-particle energy and the chemical potential (equal to the Fermi energy $E_F$). The $E_k$ are now the HFB quasiparticle energies. The (sub)matrices $U$ and $V$ determine uniquely the HFB quasiparticle operator. In the present work, the iterative procedure to obtain a self-consistent solution to the HFB equation (9) starts with the Saxon-Woods single-particle potential [9] as the initial approximation to $V^{\text{np}}(\mathbf{r})$, and is described in detail in Ref. [6].

The selection rules for a Gamow-Teller transition are that the magnitude of the change in spin and isospin must equal 0 or 1 (not 0 $\rightarrow$ 0), and that the nuclear parity must be conserved. The matrix elements of the nuclear Gamow-Teller transitions for a $\beta^-$ decay from an initial state $|N_i\rangle$ to the final state $|N_f\rangle$ may be expressed as

$$
M_{\bar{\mu}} = \langle N_f | \sum_{j=1}^4 \delta(j) \varepsilon^-(j) | N_i \rangle.
$$

(10)

Using the spherical coordinate representation, the Gamow-Teller matrix elements may be decomposed into some geometric factor and a reduced matrix [10]

$$
M_{\bar{\mu}} = -c_\lambda J_i M_i \mu | J_i M_f \rangle \frac{\langle N_f | \sum_{j=1}^4 \delta(j) \varepsilon^-(j) | N_i \rangle}{\sqrt{2J_i + 1}},
$$

(11)

where the axial vector renormalization constant $c_\lambda = 1.26$ [11], and the parent nuclear spin $J_i = 0$ in this investigation. The reduced transition probability $B_{GT}$ is defined as

$$
B_{GT} = \frac{|M_{\bar{\mu}}|^2}{2J_i + 1}.
$$

(12)

The total half-life $T_{1/2}$ may be obtained by summation over all energetically allowed transitions

$$
\frac{1}{T_{1/2}} = \sum_{n} \frac{1}{t_n} c_\lambda^2 \sum_n f_n B_{GT} (n),
$$

(13)

where $D = 6146.6 \pm 7\,\text{s}$ [12].

In the pn-QRPA model, the excitation from the parent nucleus into the daughter nucleus is mediated through the creation of pn-QRPA phonons [13]

$$
A^{+\pm}_\omega = \sum_{\mathbf{p}} \sum_{\mathbf{p}^\prime} \mathbf{X}^{\text{pm}}_{\mathbf{q} \mathbf{p} \mathbf{p}^\prime} \mathbf{A}^{\pm}_{\mathbf{p}} \mathbf{A}^{\pm^*}_{\mathbf{p}^\prime} - Y^{\text{pm}}_{\mathbf{q} \mathbf{p} \mathbf{p}^\prime} \mathbf{A}^{\pm}_{\mathbf{p}} \mathbf{A}^{\pm^*}_{\mathbf{p}^\prime},
$$

(14)

where $X$ and $Y$ are called forward (p-h) and backward (h-p) amplitudes, respectively, with $\omega$ being the phonon energy and $\mu$ the phonon multipolarity, which in the Gamow-Teller case
III. RESULTS AND DISCUSSION

The reference Lipkin-Nogami gap parameters in Dy\textsuperscript{168} for proton and neutron are 1.05 and 0.84, respectively, and these are reproduced exactly in the ground state calculation. The calculated binding energy is 1364 MeV, reproducing well the experimental value of 1363 MeV [21], giving a deviation of 0.07 per cent. Figure 2 shows the calculated and experimental reduced transition probabilities, \( B_{\text{GT}} \), as a function of excitation energy in daughter nucleus relative to the \( 1^+ \) state. Our result reproduces exactly two Gamow-Teller transitions as expected having the correct relative magnitudes of the reduced transition probabilities. The calculated energy difference of both Gamow-Teller transitions and their reduced transition probabilities are smaller by a factor of about two compared to experimental data. As shown in Table 1, the calculated total half-life is about one third of the experimental value, which is not satisfactory, while the calculated decay energy of 1.63 MeV is close to the experimental 1.4 MeV.

IV. CONCLUSIONS

In summary, the complex \( \beta^- \) decay in the nucleus Dy\textsuperscript{168} has been described using the proton-neutron Quasiparticle Random Phase Approximation (pn-QRPA) on a BCS quasiparticle basis, taking into account the Gamow-Teller transitions only. In view of the rather crude approximation made and the lack of accuracy in most previous microscopic beta decay calculations, the results are encouraging and motivate more extensive calculations to include other complex nuclear beta decays.
